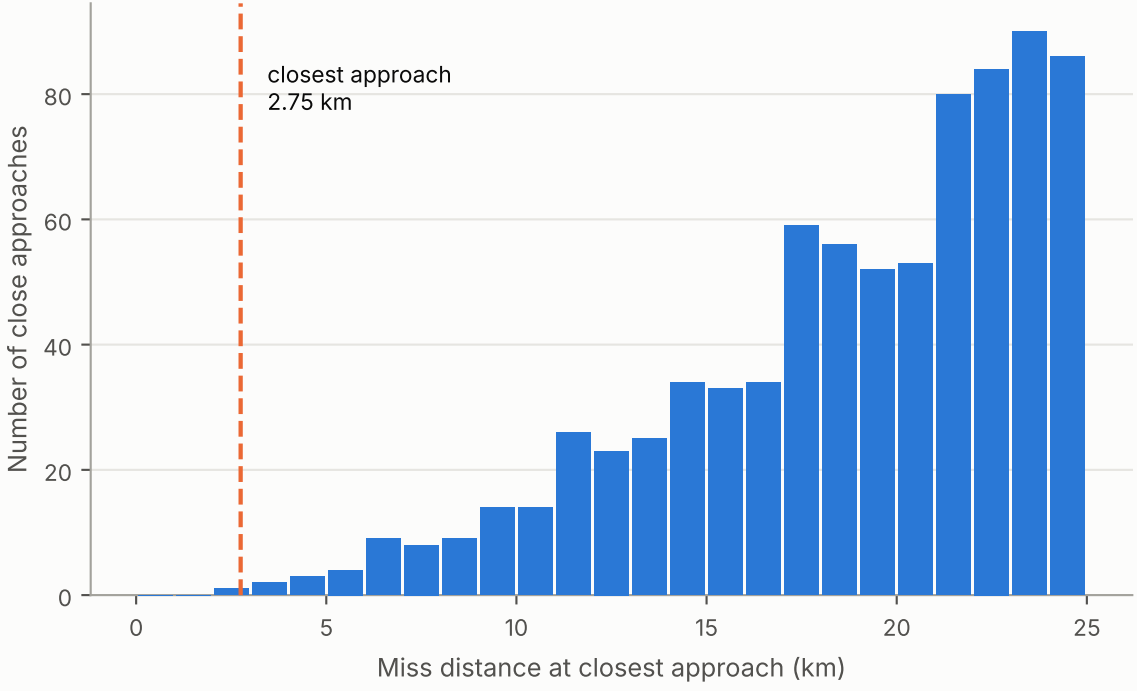
Starlink vs Kuiper: 799 close approaches over 24h, none above the risk threshold



11,104 real catalogued objects, screened 2026-09-10T07:58:00+00:00. Highest cross-operator Pc: 2.2e-10 (threshold 1e-04). Counts rise with distance because the volume of space being screened grows with it, and the series stops at 25 km because that is the screening cut-off — neither is a property of the orbits. The left-hand tail is the part that matters operationally.
