

Starlink vs Kuiper: 649 close approaches over 24h, none above the risk threshold

11,104 real catalogued objects, screened 2026-09-19T08:33:29+00:00. Highest cross-operator Pc: $3.6e-14$ (threshold $1e-04$). Counts rise with distance because the volume of space being screened grows with it, and the series stops at 25 km because that is the screening cut-off — neither is a property of the orbits. The left-hand tail is the part that matters operationally.
